Black rings from fluid mechanics

Subhaneil Lahiri

May 1, 2009
General relativity makes sense in any $\#$ of dimensions.

$D$ is a parameter.

We vary parameters to understand the theory better: c.f. coupling constants, gauge groups, . . .

Sometimes we need extra dimensions: string theory, large extra dimensions scenarios, . . .

Is gravity the same in $D > 4$?
Black holes in four vs. five dimensions

In four dimensions there are horizon topology and black hole uniqueness theorems.

In five dimensions, we are allowed an $S^1 \times S^2$ horizon as well – the black ring.

For a range of energies and angular momenta, it is possible to have two black ring and one black hole solutions - violating uniqueness.

[Emparan, Reall]
Higher dimensions

For $D \geq 6$: no exact solutions (except Myers-Perry). Approximate solutions for $R_{S^1} \gg R_{S^3}$.

[Emparan et al.]
For $D \geq 6$: no exact solutions (except Myers-Perry). Approximate solutions for $R_{S^1} \gg R_{S^3}$.

4. Three dimensional configurations
5. Higher dimensional generalisations
6. Summary
Plasmaball setup

Plasmaballs in confining theories

Plasmaballs are a bubble of deconfined phase, surrounded by confined phase, held together by surface tension.

Focus on theories that come from compactifying conformal theories on a Scherk-Schwarz circle.

Leads to confining theory.
At low temperatures, gravity dual: AdS soliton:

$$ds^2 = \frac{R_{\text{AdS}}^2}{z^2} \left( -dt^2 + F_{R\theta}(z) \, d\theta^2 + d\vec{x}^2 + \frac{1}{F_{R\theta}(z)} \, dz^2 \right),$$

where $F_a(u) = 1 - \left( \frac{\pi z}{a} \right)^4$ and $R_{\text{AdS}}^2 = \sqrt{\lambda \alpha'}$. [Witten]

Small $z$: Poincaré AdS$_5$ with one compact direction.

At $z = R_{\theta}/\pi$, the $\theta$ circle contracts: space stops.
Deconfined phase

At high temperatures: the black brane:

\[ ds^2 = \frac{R_{\text{AdS}}^2}{z^2} \left( -F_\beta(z) \, dt^2 + d\theta^2 + d\vec{x}^2 + \frac{1}{F_\beta(z)} \, dz^2 \right). \]

Horizon at \( z = \frac{\beta}{\pi} \). Temperature: \( T = 1/\beta \).
Deconfined phase

At high temperatures: the black brane:

\[ ds^2 = \frac{R_{\text{AdS}}^2}{z^2} \left( -F_\beta(z) \, dt^2 + d\theta^2 + d\vec{x}^2 + \frac{1}{F_\beta(z)} \, dz^2 \right). \]

Horizon at \( z = \frac{\beta}{\pi} \). Temperature: \( T = 1/\beta \).

Dominant phase above transition temperature, \( T_c = \frac{1}{R_\theta} \).

The equation of state of the dual plasma can be found from this gravity solution.

\[ P = \frac{\alpha}{T_c} \left( T^4 - T_c^4 \right). \]
On the bulk side, deep interior looks like black brane. Far from the plasmaball, it looks like the AdS soliton. There is a domain wall that interpolates between the two.

In the limit of infinitely large radius, a numerical domain wall solution has been found. The surface tension and thickness can be computed from this solution. [Aharony, Minwalla, Wiseman]
The Scherk-Schwarz circle does not contract in the black brane region but does contract in the AdS soliton region.

Horizon topology: fibre circle over the plasmaball, contracting at surfaces.
The equations of motion are $\nabla_\mu T^{\mu\nu} = 0$. The dynamical input is in specifying $T^{\mu\nu}$.

For long wavelengths, we need only go up to one derivative terms:

$$T^{\mu\nu} = T^{\mu\nu}_{\text{perfect}} + T^{\mu\nu}_{\text{dissipative}}.$$

Coefficients depend on $T$. Determined from static black brane.

This approximation breaks down at surfaces – but at scales $\gg$ surface thickness we can replace these regions with a $\delta$-function localised surface tension.
Three dimensional configurations

Rigid rotation: \((u^t, u^r, u^\phi) = \gamma(1, 0, \Omega)\), where
\[
\gamma = \frac{1}{\sqrt{1-v^2}}.
\]
Centripetal force provided by pressure gradient.
Three dimensional configurations

Rigid rotation: \((u^t, u^r, u^\phi) = \gamma(1, 0, \Omega)\), where \(\gamma = \frac{1}{\sqrt{1-v^2}}\).

Centripetal force provided by pressure gradient.

We find \(T^{\mu\nu}_{\text{dissipative}} \propto \vec{\nabla}(T/\gamma)\).
Three dimensional configurations

Rigid rotation: \((u^t, u^r, u^\phi) = \gamma (1, 0, \Omega)\), where \(\gamma = \frac{1}{\sqrt{1-\nu^2}}\).

Centripetal force provided by pressure gradient.

We find \(T_{\text{dissipative}}^{\mu\nu} \propto \vec{\nabla}(T/\gamma)\).

Interior: e.o.m. \(\nabla_\mu T^{\mu\nu}_{\text{perfect}} \propto \vec{\nabla}(T/\gamma) = 0\).
Rigid rotation: \((u^t, u^r, u^\phi) = \gamma(1, 0, \Omega)\), where \(\gamma = \frac{1}{\sqrt{1-v^2}}\).

Centripetal force provided by pressure gradient.

We find \(T_{\text{dissipative}}^{\mu\nu} \propto \vec{\nabla}(T/\gamma)\).

Interior: e.o.m. \(\nabla_\mu T_{\text{perfect}}^{\mu\nu} \propto \vec{\nabla}(T/\gamma) = 0\).

Surfaces: \(P = \pm \frac{\sigma}{r}\). Relates \((T/\gamma)\) to \(\Omega\) and position of surface.
We find two types of solution:

Plasmaballs

Plasmarings

\[ B^2 \]

\[ S^1 \times B^1 \]
Solutions

We find two types of solution:

**Plasmaballs**

\[
S^1 \rightarrow S^3 \\
\downarrow \quad B^2
\]

**Plasmarings**

\[
S^1 \rightarrow S^1 \times S^2 \\
\downarrow \quad S^1 \times B^1
\]
We compute the thermodynamic properties of the whole solution with

\[ E = \int d^2 x \ (T^{tt}), \]

\[ L = \int d^2 x \ (r^2 T^{t\phi}), \]

\[ S = \int d^2 x \ (\gamma s). \]
We compute the thermodynamic properties of the whole solution with

\[ E = \int d^2x \left( T^{tt} \right) , \]

\[ L = \int d^2x \left( r^2 T^{t\phi} \right) , \]

\[ S = \int d^2x \left( \gamma s \right) . \]

Then we compute an overall temperature and angular velocity via

\[ dE = T dS + \Omega dL , \]

we find

\[ T = \frac{T}{\gamma} , \quad \Omega \text{ as before} . \]
Phase diagram

![Phase diagram with curves for Ball, Small ring, and Large ring. The axes are labeled \( \tilde{S} \) and \( \tilde{L} \).]
Phase diagram

\[ \tilde{S} \]

\[ \tilde{L} \]

\[ \frac{GS}{(GM)^{3/2}} \]

\[ \frac{GJ}{(GM)^{3/2}} \]

- Large black ring
Topologies in six dimensions

$S^4 \quad S^3 \times S^1$

$S^2 \times S^2 \quad S^2 \times T^2$
Topologies in six dimensions

\[ S^4 \downarrow B^3 \]
\[ S^3 \times S^1 \downarrow B^2 \times S^1 \]
\[ S^2 \times S^2 \downarrow B^1 \times S^2 \]
\[ S^2 \times T^2 \downarrow B^1 \times T^2 \]
Topologies in six dimensions

\[ S^4 \downarrow B^3 \]

\[ S^3 \times S^1 \downarrow B^2 \times S^1 \]

\[ S^2 \times S^2 \downarrow B^1 \times S^2 \]

\[ S^2 \times T^2 \downarrow B^1 \times T^2 \]
Solving equations of motion

Again: rigid rotation \((u^t, u^r, u^\phi, u^z) = \gamma(1, 0, \Omega, 0)\).

Again: \(\frac{T}{\gamma} = T = \text{constant}\).

Now: surface satisfies \(P = \sigma K^\mu_\mu\).
Ordinary balls
Pinched balls

\[

Topologies in seven dimensions

\[
\begin{align*}
&S^5 & S^4 \times S^1 & S^3 \times T^2 \\
&S^3 \times S^2 & S^2 \times S^2 \times S^1 & S^2 \times T^3
\end{align*}
\]
Topologies in seven dimensions

$S^5 \downarrow B^4$

$S^4 \times S^1 \downarrow B^3 \times S^1$

$S^3 \times T^2 \downarrow B^2 \times T^2$

$S^3 \times S^2 \downarrow B^1 \times S^3$

$S^2 \times S^2 \times S^1 \downarrow B^1 \times S^2 \times S^1$

$S^2 \times T^3 \downarrow B^1 \times T^3$
Higher dimensional generalisations

Approximate solutions

For ring, $B^3 \times S^1$, take $\epsilon = \frac{R_{B^3}}{R_{S^1}}$ small.

For ‘torus’, $B^2 \times T^2$, take $\epsilon = \frac{R_{B^2}}{R_{T^2}}$ small.

Expand in $\epsilon$. At $\mathcal{O}(\epsilon^0)$ – just a tube.

Similar to black-fold construction of Emparan et al.

We can get insight to some problems in classical gravity from fluid mechanics in AdS/CFT.

In five dimensions – qualitative agreement with flat space gravity.

In six dimensions – proposal for phase diagram.

In seven dimensions – new topology.

Future: numerical solutions for $D = 7$, phase diagram.

Gregory-Laflamme vs. Plateau-Rayleigh. [Caldarelli et al.]
